**CALCULATING ENERGY COST TO OPERATE A COMPRESSOR****Annual Electricity Cost:**

$$[\text{Horsepower} \times 0.746 \times \text{Hours} \times \text{Electricity Cost}] / \text{Motor Efficiency}$$
**Where:**

Horsepower (hp) = motor full load horsepower

1hp = 0.746kW

Hours = number of hours that the compressor operates

Electricity Cost = \$/kWh (Add in demand charges and calculate average \$/kWh)

Motor Efficiency = motor nameplate full load efficiency can vary from 75-95%

**Example 1:**

What is the annual electricity cost to operate a fully loaded 200hp compressor that runs 40% of the time (3,500 hrs/yr)? Motor efficiency is assumed to be 85%, so the compressor is drawing approximately 175kW. The electricity cost is \$0.08/kWh. If the monthly demand charge is \$10/kW - then the customer will be charged \$1,700/month in addition to the kWh usage cost (51,040 kWh with the above assumptions). For this situation the overall average cost of electricity including the kWh use and demand charge is approximately \$0.114/kWh.

$$\text{Annual Electricity Cost} = [\text{hp} \times 0.746 \times \text{Hrs} \times \text{Electricity Cost}] / \text{Motor Efficiency}$$

$$\text{Annual Electricity Cost} = [200\text{hp} \times 0.746\text{kW}/\text{hp} \times 3,500\text{hrs} \times \$0.114/\text{kWh}] / 0.85$$

**Annual Electricity Cost = \$70,036**

If the motor in the above example were increased to 92% efficiency, the annual electricity cost would be reduced to **\$64,707**.

**Example 2:**

Let's say that you want to make a more precise calculation for a three-phase compressor. Example 1 does not include system losses for belts, fans, pumps, etc. Therefore, it is more accurate to measure input kW using line-to-line voltage and current. Using the same scenario where the compressor runs 40% of the time (3,500 hrs/yr) full load amps, line-to-line voltage and power factor are all measured in this case. Electricity cost is \$0.095/kWh. The monthly demand charge is \$10/kW - the overall average cost of electricity with demand charge is approximately \$0.095/kWh.

Full load amps = 280 amps

Line-to-line voltage = 460volts

Power Factor = pf = 0.82

First, find the kW usage for the three-phase motor:

kW =

$$[\text{volts} \times \text{amps} \times \text{pf} \times 1.732] / 1,000 = [460 \times 280 \times 0.82 \times 1.732] / 1,000 = 183\text{kW}$$

$$\text{Annual Electricity Cost} = \text{kW} \times \text{Hrs} \times \text{Electricity Cost}$$

$$\text{Annual Electricity Cost} = 183\text{kW} \times 3,500\text{hrs} \times \$0.095/\text{kWh}$$

**Annual Electricity Cost = \$60,848**

Note that in the second example, the electricity measurements are made in the circuit leading to the compressor motor, so that the full power usage is measured. However, the motor efficiency is still a factor when one considers a possible motor change out, as noted in example one.

**What does it cost me per CFM (cubic foot per minute of compressed air)?**

**Example 3:**

The following provides a ballpark estimate for a typical compressor running 6,000 hours annually, as 90% efficient motor and that a typical compressor produces 4 CFM per 1hp. Electricity cost is assumed \$0.08/kWh.

$$1\text{CFM} = 0.25\text{hp} = 0.25\text{hp}/0.90 \times 0.746\text{kW}/\text{hp} = 0.207\text{kW}$$

$$1\text{CFM} = 0.207\text{kW} \text{ (assuming a 90\% efficient motor)}$$

$$\text{Annual Electricity Cost for 1 CFM} = \text{kW} \times \text{Hrs} \times \text{Electricity Cost}$$

$$\text{Annual Electricity Cost for 1 CFM} = 0.207\text{kW} \times 6,000\text{hrs} \times \$0.08/\text{kWh}$$

$$\text{Annual Electricity Cost for 1 CFM} = \$99.50 \text{ approximately } \$100/\text{CFM}$$

**Other Compressor Costs**

Don't forget to factor in equipment capital costs, maintenance costs, water supply costs (for water coolers), and any overhead costs for floor space, insurance etc.

**Conclusion**

Compressors are expensive to run!! Compressed air is necessary for many plant processes, but it is an inefficient source of energy. You need 7 to 8hp of electrical power into the compressor to operate a 1 motor. The overall efficiency of a typical compressed air system can be as low as 10 to 15 percent! If that your system is well designed, operates in an efficient manner, and system leakage is minimized.
